31 **Abstract**

32 About 200 second-hand plastic toys sourced in the UK have been analysed by x-ray  
33 fluorescence spectrometry for hazardous elements (As, Ba, Cd, Cr, Hg, Pb, Sb, Se)  
34 and Br as a proxy for brominated flame retardants. Each element was detected in > 20  
35 toys or components thereof with the exception of As, Hg and Se, with the frequent  
36 occurrence of Br, Cd and Pb and at maximum concentrations of about 16,000, 20,000  
37 and 5000  $\mu\text{g g}^{-1}$ , respectively, of greatest concern from a potential exposure  
38 perspective. Migration was evaluated on components of 26 toys under simulated  
39 stomach conditions (0.07 M HCl) with subsequent analysis by inductively coupled  
40 plasma spectrometry. In eight cases, Cd or Pb exceeded their migration limits as  
41 stipulated by the current EU Toy Safety Directive (17 and 23  $\mu\text{g g}^{-1}$ , respectively),  
42 with Cd released from yellow and red Lego bricks exceeding its limit by an order of  
43 magnitude. Two further cases were potentially non-compliant based on migratable Cr,  
44 with one item also containing > 250  $\mu\text{g g}^{-1}$  migratable Br. While there is no retroactive  
45 regulation on second-hand toys, consumers should be aware that old, mouthable,  
46 plastic items may present a source of hazardous element exposure to infants.

47

48

49

50

51 **Introduction**

52 Mounting evidence for their acute and chronic toxicities at relatively low doses has  
53 resulted in increasingly restricted use of many heavy metals and metalloids in  
54 consumer products over the past few decades (1,2). Young children are particularly  
55 susceptible to the health impacts of such elements because of their higher metabolic  
56 rate, greater surface area to weight ratio, more rapid growth of organs and tissues, and  
57 longer time period to develop diseases with latency periods compared with adults (3).  
58 Infants are also potentially exposed to greater quantities of metals and metalloids in  
59 consumer products through the mouthing of non-food objects as they seek oral  
60 stimulation and explore taste, texture and shape. Consequently, products designed to  
61 be used by (or in contact with) young children have received particularly stringent  
62 regulatory attention in terms of both the concentrations and migratabilities of toxic  
63 chemicals in accessible components.

64

65 The original European Council Directive 88/378/EEC on toy safety (4) stipulated  
66 migratable limits for eight hazardous elements, listed in Table 1, that are based on the  
67 ingestion of a small quantity of material and defined by two-hour extraction under  
68 simulated gastric conditions (dilute HCl at 37 °C) according to the European standard,  
69 EN 71-3 (5). An amended directive that applied to products placed on the market from  
70 July 2013 provided revised limits on migration in dilute HCl that depended on the  
71 matrix being tested (liquid or sticky; brittle, powder-like or pliable; material that can  
72 be scraped off) (see Table 1), as well as limits for an additional number of elements  
73 and different oxidation states of Cr (6). Precise concentration limits for some elements  
74 have since been revised downwards in line with new scientific data, and there is  
75 currently a proposal to substantially reduce the concentration limits of Pb because of a

76 growing body of scientific evidence that suggests there is no lower threshold of safety  
 77 for its levels in blood (7).

78

79 *Table 1: Migratable limits (in  $\mu\text{g g}^{-1}$ ) of eight hazardous elements in toys and as*  
 80 *defined by the original and amended EC Toy Safety Directives. Note that different*  
 81 *species of Cr are discriminated in the latter directive, and that limits for Ba, Cd and*  
 82 *Pb have since undergone (or are currently being proposed for) further reduction, with*  
 83 *revised values shown in parentheses.*

	88/378/EEC	2009/48/EC		
		brittle, powder, pliable	liquid, sticky	scraped-off
As	25	3.8	0.9	47
Ba	1000	4500 (1500)	1125 (375)	56000 (18,750)
Cd	50	1.9 (1.3)	0.5 (0.3)	23 (17)
Cr	60			
Cr (III)		37.5	9.4	460
Cr(VI)		0.02	0.005	0.2
Hg	60	7.5	1.9	94
Pb	90	13.5 (2.0)	3.4 (0.5)	160 (23)
Sb	60	45	11.3	560
84 Se	500	37.5	9.4	460

85

86 While the current Toy Safety Directive applies to new products, there is no retroactive  
 87 regulation on the recycling or re-sale of older toys. Second-hand toys are an attractive  
 88 option because they can be inherited directly from relatives and friends or obtained  
 89 cheaply and readily from charity stores, flea markets and the internet (8). Moreover,  
 90 in the UK the re-use of working, old and outgrown toys is actively encouraged  
 91 through the Toy Recycling in Your Community ('Tric') scheme (9). Whereas liquid  
 92 or sticky toys have a limited shelf-life and parents are likely to be wary of second-  
 93 hand toys that are brittle or have visibly flaking paint, old plastic products often  
 94 appear to be in good condition, presumably because of the durability of synthetic

95 polymers and the color-fastness of many pigments, and tend to be re-used more  
96 extensively.

97

98 Despite the market for second-hand plastic toys and their abundance in homes,  
99 waiting rooms, day-care centers and nurseries (8), there has been little scientific study  
100 of the presence of hazardous elements in such items. Specifically, two studies  
101 conducted in the US and employing a handheld x-ray fluorescence (XRF)  
102 spectrometer report total concentrations of Pb in a variety of vintage plastic toys from  
103 day centers and family homes that exceeded US limits of  $100 \mu\text{g g}^{-1}$ , but migration  
104 from the matrix was not evaluated (8,10). Other metals and metalloids, including As,  
105 Ba, Cd and Cr, are mentioned in the latter study, but none of these elements have US  
106 mandatory limits in toys with the exception of Cd in jewelry.

107

108 The present study describes the first systematic investigation of the occurrence and  
109 migratability of hazardous elements in second-hand plastic toys in the UK. Portable  
110 XRF was used to determine the concentrations of the eight elements listed in the  
111 original toy Safety Directive (and defined in Table 1) in addition to Br as a proxy for  
112 brominated flame retardants (BFRs) and whose concentration is limited in electronic  
113 plastic waste according to EU Directive 2002/95/EC (11). Based on the XRF results,  
114 selected samples were subjected to extraction in dilute HCl in order to evaluate  
115 element migratability and potential for exposure through ingestion.

116

## 117 **Experimental Section**

118 *Sample collection and categorization*

119 About 200 toys that were designed for young children, containing parts that were  
120 small or accessible enough to be mouthed in part or in whole and that had been  
121 acquired second-hand or second-generation, were sourced from two pre-school  
122 nurseries, a primary school, various charity shops and five family homes within the  
123 city of Plymouth, south west England. Toys were constructed entirely or largely of  
124 synthetic, molded plastic (and not foam, rubber or textile) and excluded products that  
125 housed electrical parts or that had been painted. Products and distinct components  
126 thereof (e.g. different colored blocks, various body parts of figures, separate  
127 constituents of games and puzzles) are listed in Table S1 of the Supporting  
128 Information where they are categorized as follows: ‘activity’ (balls, marbles, yoyos,  
129 tools, letters), ‘cars and trains’ (and other toys with wheels, plus accessories),  
130 ‘construction’ (blocks and studded bricks), ‘food-related’ (bottle caps, cutlery,  
131 crockery, model food), ‘figures’ (animals, dinosaurs, dolls, characters), ‘games and  
132 puzzles’ (board games, shape sorters, numeracy toys), ‘jewelry’ (straps, beads, rings)  
133 ‘sound-generating’ (rattles, whistles, bells, musical instruments) and ‘water’ (mainly  
134 bath toys).

135

### 136 *XRF analysis*

137 Toys and components were analysed by energy-dispersive FP-XRF using a Niton  
138 XL3t 950 He GOLDD+ that was configured nose-upwards in the laboratory and in a  
139 4000 cm<sup>3</sup> Thermo Scientific accessory stand. The instrument was operated in a low-  
140 density, ‘plastics’ mode with thickness correction down to 50 µm. A suite of elements  
141 may be determined in this mode but the present study focuses on the eight metals and  
142 metalloids defined in the original Toy Safety Directive (listed in Table 1) and that are

143 generally regarded as most hazardous for children (12), as well as Cl and Br as  
144 indicators of polyvinyl chloride (PVC) BFRs, respectively.

145

146 Where possible, sample thickness was determined through the measurement surface  
147 using 300 mm Allendale digital calipers, while for hollow objects (mainly dolls, balls,  
148 model food and sound-generating items) thickness was estimated from accessible  
149 surfaces of objects of similar construction and rigidity. Samples were placed on the  
150 stainless steel base plate of the accessory stand with the measurement surface above  
151 the XRF detector window before analyses with appropriate thickness correction and  
152 collimation (3 mm or 8 mm beam width depending on the accessibility and  
153 homogeneity of the area to be probed) were activated remotely through a laptop for  
154 counting periods of 40 s at 50 kV/40  $\mu$ A (main energy) and 20 s at 20 kV/100  $\mu$ A  
155 (low energy). Spectra were quantified by fundamental parameters yielding elemental  
156 concentrations in parts per million ( $\mu$ g  $g^{-1}$ ) and with a counting error of  $2\sigma$  that were  
157 downloaded to the laptop via Niton data transfer (NDT) software.

158

159 Measurement detection limits (as  $3\sigma$ ) varied depending on sample thickness and  
160 composition, but median values based on counting errors arising from analyses that  
161 failed to deliver a concentration ranged from  $< 10 \mu$ g  $g^{-1}$  for As, Br and Pb to about  
162  $300 \mu$ g  $g^{-1}$  for Ba. (A complete list of detection limits can be found in Table S1.)  
163 Polyethylene and polyvinyl chloride (PVC) reference discs of 13-mm thickness and  
164 that had been impregnated with As, Ba, Cd, Cr, Hg, Pb, Sb and Se (PN 180-619,  
165 LOT#T-81), Cd, Cr, Br, Hg and Pb (PN 180-554, batch SN PE-071-N) or Br and Sb  
166 (PVC-4C80) were analysed at regular intervals throughout each measurement session  
167 and returned concentrations that were always within 10% of mean certified values. A

168 detailed comparison of metal concentrations in plastics derived by portable XRF and,  
169 as an independent measure, by inductively coupled plasma (ICP) spectrometry  
170 following digestion in H<sub>2</sub>SO<sub>4</sub>, is given elsewhere (13).

171

#### 172 *Sample extraction*

173 Based on the results of XRF analysis, and subject to sufficient accessible material and  
174 permission to sacrifice, 34 components of 26 plastic toys (and as described in Table  
175 S1) were extracted in dilute HCl according to EN 71-3 for scraped off material (5).  
176 Hard plastics were fractionated to < 2 mm through a stainless steel grater, with 100 to  
177 300 mg of material collected on white A4 paper subsequently transferred to a series of  
178 pre-weighed 50 ml polypropylene centrifuge tubes with the aid of a Nylon brush;  
179 softer plastics (mainly PVC) or thin items were cut into small (< 5 mm) pieces using  
180 stainless steel scissors or a scalpel before being transferred to centrifuge tubes  
181 likewise. Ten ml of a solution of 0.07 M HCl, simulating the human gastric  
182 environment and prepared by dilution of Fisher Scientific Trace Analysis grade acid  
183 in Elga ultrapure water, was then pipetted into each tube and the screw-capped  
184 contents inverted twice before being placed in a water bath at 37 °C for 2 h (1 h under  
185 lateral agitation and 1 h without agitation). At the end of the incubations, 5 ml from  
186 each tube were filtered through Whatman 0.45 µm PES syringe-cartridge filters into  
187 10 ml polypropylene centrifuge tubes and diluted to 10 ml with 0.07 M HCl.

188

#### 189 *Extract analysis*

190 Within 24 h of preparation, extracts were analysed for As, Ba, Br, Cd, Cr, Hg, Pb, Sb  
191 and Se by ICP mass spectrometry using a Thermo X-series II (Thermo Elemental,  
192 Winsford UK) with a concentric glass nebulizer and conical spray chamber. The

193 instrument was calibrated externally using five mixed standards prepared by serial  
194 dilution of mixed standard solutions (LabKings, Hilversum, NL) in 0.07 M HCl, and  
195 internally by the addition of 10  $\mu\text{g L}^{-1}$  of  $^{115}\text{In}$  and  $^{193}\text{Ir}$  to all samples, standards and  
196 blanks. RF power was set at 1400 W and coolant, auxiliary, nebulizer and collision  
197 cell gas flows rates were 13 L Ar  $\text{min}^{-1}$ , 0.70 L Ar  $\text{min}^{-1}$ , 0.75 L Ar  $\text{min}^{-1}$  and 3.5 mL  
198 7%  $\text{H}_2$  in He  $\text{min}^{-1}$ , respectively. Data were acquired over a dwell period of 10 ms,  
199 with 50 sweeps per reading and three replicates. Limits of detection, based on three  
200 standard deviations about multiple measurements of blanks ranged from 0.05  $\mu\text{g L}^{-1}$   
201 for Cd and Pb to about 10  $\mu\text{g L}^{-1}$  for Br. Analyses of a reference drinking water (EP-  
202 L-2; SPC Science, Quebec) after every ten samples revealed analyte concentrations  
203 that were within 10% of certified values with the exception of Sb (within 15%).

204

## 205 **Results**

### 206 *Sample categorization and elemental concentrations*

207 The number and categorization of plastic toys and components considered in the  
208 present study is summarized in Table 2. Thus, 285 XRF analyses were performed on  
209 197 products, with multiple measurements undertaken on distinctly different  
210 components of various toys like the wheels, base and body of a car, different colored  
211 blocks in a set, and the constituent parts of a puzzle or game. Overall, 28 products  
212 were constructed of PVC (defined by the XRF as having a Cl content greater than  
213 15% by weight; 14), with the majority of this polymer encountered in the figures and  
214 water categories. Also shown in Table 2 is the number of measurements in which each  
215 hazardous element was detected by XRF. Thus, Hg was not detected in the products  
216 analysed, and the sequence of decreasing number of cases detected among the  
217 remaining elements was: Ba > Br/Cr > Sb > Cd/Pb > As > Se; with Ba and Br

218 encountered across all categories considered. Hazardous elements were most  
219 frequently detected among plastic figures, construction toys, games and puzzles, and  
220 jewelry, where, on average, more than one element was detected per measurement,  
221 and detection was least frequent among activity products, cars and trains and toys  
222 designed for use in water.

223

224 The total concentrations of each element, where detected by XRF, are illustrated in  
225 Figure 1 in ascending order, with PVC- and non-PVC-based materials discriminated  
226 and statistical summaries for each dataset annotated. Also shown is the number of  
227 cases in which total concentrations exceed the respective migratable limits defined by  
228 Directive 2009/48/EC and its subsequent amendments (see Table 1). (Note that the  
229 higher migratable limit for Cr in its lower oxidation state is shown and, while Br is  
230 not included in the Toy Safety Directive, the value presented is based on the  
231 Restriction of Hazardous Substances concentration limit for certain brominated flame  
232 retardants, but not total Br, in electronic plastics; 11.) While the two measures are not  
233 directly comparable, total concentrations that exceed migratable limits should act as a  
234 trigger for further investigation of a product. Thus, overall, there were 73 cases of  
235 exceedance, encompassing 49 measurements and 31 products (of which seven were  
236 PVC-based) from all categories with the exception of toys designed for water. Co-  
237 associations of multiple elements exceeding their respective limit values were  
238 encountered in two types of bead (Br-Cd-Pb-Sb), a number of Lego bricks (Cd-Se or  
239 Cr-Sb), a small games mat (Ba-Pb), various games counters (Cd-Se) and figures (Cd-  
240 Pb), and the plastic bowl of a bell (Cr-Sb).

241

242 *Table 2: Quantity and categorization of toy samples, along with the number of*  
 243 *analyses performed and the number of cases in which each hazardous element was*  
 244 *detected.*

246

247 *Hazardous element migratability*

248 Extraction tests were performed on 34 components of 26 toys that could be sacrificed  
 249 and that were homogeneous, readily accessible and yielded sufficient quantities of  
 250 plastic material on grating or slicing. These included many of the items where the  
 251 XRF returned one or more hazardous element above its corresponding EU Directive  
 252 migration limit (Table 1) in order to ascertain compliance/non-compliance, and  
 253 samples of lower elemental concentrations but of a variety of color and type in order  
 254 to explore possible controls on and variations in migratability. Significantly, and  
 255 despite constraints on the amount of material required for extraction, a number of  
 256 items tested (e.g. small blocks, counters and beads) were small enough to be ingested  
 257 whole.

258

259 Table 3 presents results for all samples in which at least one element was detected in  
 260 the extract by ICP ( $n = 30$ ) in terms of both weight-normalized migratable  
 261 concentration and percentage migration relative to total elemental content (i.e. a  
 262 measure of bioaccessibility). Note that where the element was detected in the extract

263 but not by XRF, a lower limit of bioaccessibility is given that is based on the detection  
264 limit returned by the Niton XL3t (and as shown in Table S1). Thus, while As and Se  
265 were never detected in the extracts, Ba and Cd were encountered in 30 and 11 cases,  
266 respectively, and in a variety of toys. Migratable concentrations ranged from  $< 1 \mu\text{g g}^{-1}$   
267 <sup>1</sup> for Cd in two components to  $> 100 \mu\text{g g}^{-1}$  for Ba, Br, Cd, Pb and Sb in at least one  
268 case each, and bioaccessibility ranged from below 1% for Ba, Cd and Cr in a number  
269 of products to over 10% for Cr in a molded food toy and Pb in a black bead. Among  
270 the elements considered, and despite variations in percentage bioaccessibility,  
271 statistically significant correlations between migratable concentrations and total  
272 concentrations were exhibited by Cd ( $n = 11, r = 0.825, p = 0.002$ ) and Pb ( $n = 7, r =$   
273  $0.972, p < 0.001$ ).

274

275 With respect to the current EU Directive, non-compliance occurred for Cd in four  
276 yellow or red building bricks from two Lego sets, and for Pb in two body parts of a  
277 PVC-based model dinosaur and on both surfaces of a child's PVC tape measure.

278 Although concentrations of extractable Cr were compliant in respect of total  
279 migration, it is suspected that a number of brightly colored items or parts (a building  
280 block, model dinosaur and tape measure) and a black bead were non-compliant in  
281 respect of Cr(VI) since the co-association of Cr and Pb suggests the presence of the  
282 pigment, lead chromate. Overall, therefore, various components from four toys were  
283 non-compliant, with a further two products potentially non-compliant.

284

285 *Table 3: Migratable concentrations (in  $\mu\text{g g}^{-1}$ ) and percentage bioaccessibilities (in*  
286 *parentheses and relative to total concentrations) of hazardous elements detected in*  
287 *the extracts of different toys or components thereof that are numbered and lettered*

288 according to the identification given in Table S1 and that are classified as PVC- or  
 289 non-PVC-based. Note that figures in bold denote non-compliance or potential non-  
 290 compliance according to the current EU Toy Safety Directive and the proposed,  
 291 revised limit for Pb.

## 294 Discussion

295 The results of the present study reveal high concentrations of many elements listed by  
 296 the original EU 88/3781/EEC Toy Safety Directive (4) in products that remain in  
 297 circulation, being handed-down by parents, recycled via charity shops, and donated to  
 298 or purchased (historically) by nurseries, hospitals and schools. Both the frequencies of  
 299 detection and median elemental concentrations are greater than corresponding values  
 300 for new plastic toys sourced from major retailers (15,16) but are more in line with

301 measurements reported for new, low cost items purchased from bargain stores and  
302 road-side vendors (16,17,18). Regarding older plastic toys, similar conclusions to the  
303 present study have been reached for Pb in toys in day care centers in Nevada (10) and  
304 for several hazardous metals in products purchased in the 1970s and 1980s in the  
305 USA but whose precise source was not specified (8). The latter studies, however,  
306 implicitly relate exposure and health hazard to total elemental concentrations in  
307 plastic, in line with current US restrictions, rather than migratable levels. The results  
308 shown in Table 3 clearly indicate a wide variation in bioaccessibility on a percentage  
309 basis for any given element, with correlations between total and migratable  
310 concentrations significant only for Cd and Pb. Presumably, this reflects variations in  
311 product composition, age and usage, but suggests that total concentration is not,  
312 necessarily, a good proxy for exposure through ingestion.

313

314 Elemental concentrations extracted by dilute HCl in this study that exceed current or  
315 proposed EU migratable limits include Cd and Pb (and potentially Cr) in various  
316 building blocks and bricks, and in PVC figures. In these products, Pb appears to have  
317 been employed in compounds used as stabilizers in PVC or, in association with  
318 Cr(VI), as the brightly colored yellow pigment,  $PbCrO_4$ , whose precise hue may be  
319 varied through to red by addition of  $PbMoO_4$  or  $PbSO_4$  (19). Cadmium was evident as  
320 a stabilizer in one PVC-based component (the black caterpillar track from an  
321 excavating vehicle) but was more generally encountered in a variety of brightly-  
322 colored toys. Here, the compound CdS, or a mixture of CdS and ZnS, is likely to have  
323 been employed as a yellow pigment, with successively darker hues of orange and red  
324 effected by the progressive replacement of S by Se (19). Consistent with this  
325 assertion, Se was absent from all yellow toys that were Cd-positive, while the mass

326 ratio of Cd:Se increased from about 4 in an orange games cup to about 7.3 in a dark  
327 red counter.  
328  
329 Cadmium and Pb-based pigments found widespread use in plastics because of their  
330 pure, brilliant shades, opacity, light-fastness and weather-resistance, and, at least  
331 when new, high chemical resistance and little tendency to migrate (20). Accordingly,  
332 such pigments had a key role in manufacture of colorful toys before health and  
333 environmental concerns resulted in their restriction and replacement by safer organic  
334 and inorganic alternatives. Of the toys analysed in the present study, the highest levels  
335 of total and migratable Cd were encountered in some, but not all, red and yellow  
336 studded Lego bricks. Specifically, those in sets that appear to have been purchased in  
337 the 1970s yielded migratable Cd concentrations that sometimes exceeded the EU  
338 migration limit by an order of magnitude, while those purchased in the 1990s, and that  
339 were visually indistinguishable from the older bricks, contained no detectable Cd. The  
340 introduction of high quantities of Cd in Lego bricks is likely to have coincided with  
341 the introduction of acrylonitrile butadiene styrene (ABS) as a replacement for  
342 cellulose acetate as the material of construction in the 1960s (21) since Cd  
343 sulphoselenides were favorable colorants for styrenic-based polymers at the time (22);  
344 when, precisely, Cd-based chemicals in Lego were subsequently replaced by safer  
345 pigments, however, is unclear. Given their popularity, durability, collectability and  
346 compatibility with newer products, older, ABS-based Lego sets, and in particular  
347 those containing brightly-colored pieces, should be treated with caution.  
348  
349 One element not embraced by the original or amended Toy Safety Directive but of  
350 concern from a health perspective is Br. Although the halogen is found in the organic

351 pigment, copper phthalocyanine green 36, that has limited use in plastics (23), its  
352 most important application in synthetic polymers is as a constituent of free radical-  
353 scavenging BFRs. These chemicals represent a wide variety of organic compounds  
354 designed to increase resistance to ignition and slow down developing fires in heat-  
355 generating materials like electronic casings and construction materials. Because many  
356 commonly-employed BFRs are persistent, bioaccumulative and toxic, their use in new  
357 and recycled electrical products is restricted according to EU Directive 2002/95/EC  
358 (11). Accordingly, and given the practical and analytical difficulties in discriminating  
359 BFRs (including those that are unregulated; 24), Br should be absent from non-  
360 electrical plastics that are not pigmented with copper phthalocyanine (14). That nearly  
361 40 non-green (and mainly neutrally-colored) products or components thereof were Br-  
362 positive in the present study, and usually at levels well below those required for flame  
363 retardancy (between about 3 and 8% by weight; 24), suggests many children's toys  
364 have been manufactured, directly or indirectly, from recycled waste electrical casings.  
365 This issue has been highlighted more generally in new consumer products, including  
366 toys (25,26,27), but the presence of Br in older toys raises the possibility that residues  
367 of the more hazardous BFRs that were banned 15 years ago and are subject to more  
368 stringent regulation, like polybrominated diphenyl ethers and polybrominated  
369 biphenyls, remain in plastics that are available to young children. Because of the  
370 relatively small molecular weight of most BFRs, they also have a greater propensity  
371 to migrate compared with many other organic additives (28). This is evident from the  
372 extraction of considerable quantities of Br from an item of jewelry presented in Table  
373 3.  
374

375 With the introduction and refinement of the Toy Safety Directive, the design and  
376 development of safer and more sustainable products, and the publicity generated by  
377 new goods violating chemical standards, there is clearly good reason for the plastic  
378 manufacturing industry to eliminate hazardous elements from new toys. The latest  
379 statistics provided by the US Consumer Product Safety Commission (29) confirm a  
380 steady decline in the number of recalls based on the presence of hazardous substances,  
381 and in particular Pb. However, the attraction of second-hand products to consumers in  
382 terms of cost, convenience and recyclability is acting as a conduit for exposing  
383 ‘legacy’ chemicals to the current generation of young children. For consumer  
384 products more generally, some authorities have advocated a ‘right to know’ policy,  
385 whereby goods are labelled should they contain any toxic constituents (3, 30).  
386 Because of the plethora and variety of old toys on sale or passed down whose precise  
387 ages and origins are unknown, this approach would be difficult to implement in the  
388 current context. However, a specific recommendation of this investigation is that  
389 consumers should be aware of the potential risks associated with small, mouthable,  
390 and brightly colored (and in particular red and yellow) old plastic toys or components.  
391 The present study has also provided evidence for the occurrence of historical BFRs in  
392 some second-hand toys that are neutrally colored; this finding is part of a broader and  
393 more complex issue concerning the recycling of electronic plastic waste and one that  
394 warrants further study (14,31).

395

#### 396 **Declaration**

397 The author declares no competing financial interests.

398

#### 399 **Acknowledgements**

400 Mr. Rupert Goddard, Dr. Andrew Fisher and Ms. Anusha Rajamani, PU, are thanked  
401 for technical and practical assistance throughout. Mr. Kev Solman and Ms. Sarah  
402 Dainty, PU, organized access to and collection of the nursery and school toys.

403

#### 404 **Associated content**

#### 405 **Supporting information available**

406 A brief description of each toy and component, XRF results with counting errors, and  
407 cases of potential non-compliance are provided in Table S1.
